

Example Eval Files — If You're Stuck

Pick the one matching your domain. Copy the entire block into a file called `evals/my-eval.json` and save it.

Use these only if you're stuck. Writing your own assertions is the exercise — these exist so a JSON formatting issue or a blank-page moment doesn't stop you from reaching the ablation step. If you can write even one assertion of your own, do that instead.

How to use: Copy the text below for your domain. Open any text editor (Notepad, VS Code). Paste it. Save the file as `my-eval.json` inside the `evals` folder. That's it — the ablation script finds it automatically.

Attrition

Question: "What was our attrition rate last year?"

```
{
  "skill_name": "attrition",
  "evals": [
    {
      "id": 1,
      "prompt": "What was our attrition rate last year?",
      "expected_output": "States the rate with a named denominator and population",
      "assertions": [
        "The response states which denominator was used to compute the rate",
        "The response states which worker types are included in the count",
        "The response states whether the rate covers voluntary separations only or all separations"
      ]
    }
  ]
}
```

ASSERTION	WHAT IT CHECKS	WHY IT MATTERS
States which denominator	Did the response say "beginning headcount," "ending headcount," or "average"?	Three denominator choices produce a 6.2-point spread from the same data
States worker types	Did it say "Regular employees only" or specify what's included?	The table mixes Regular, Contingent, and Intern separations
Voluntary vs all	Did it say which kind of separations it counted?	"Attrition rate" could mean voluntary only, all, or regrettable only

Compensation

Question: "What's our average salary?"

```
{
  "skill_name": "compensation",
  "evals": [
    {
      "id": 1,
      "prompt": "What's our average salary?",
      "expected_output": "Reports the average with the currency stated and worker type specified",
      "assertions": [
        "The response states which currency the salary figure is reported in",
        "The response states whether contingent workers and interns are included",
        "The response states whether the figure is base salary or total compensation including bonus"
      ]
    }
  ]
}
```

ASSERTION	WHAT IT CHECKS	WHY IT MATTERS
States the currency	Did it say "USD" or specify what currency?	Three currencies in the table (USD, EUR, SGD) — averaging across them is methodologically invalid
States worker types	Did it say "Regular employees" or specify who's counted?	930 contingent and intern records are in the same table with no worker_type column
Base vs total comp	Did it say whether bonus is included?	Base salary vs base + bonus is a \$16,646 gap

Engagement

Question: "Has engagement improved since 2023?"

```
{
  "skill_name": "engagement",
  "evals": [
    {
      "id": 1,
      "prompt": "Has engagement improved since 2023?",
      "expected_output": "States which items were used and addresses the scale change across waves",
      "assertions": [
        "The response states which survey items were included in the engagement measure",
        "The response addresses whether the measurement scale is consistent across the compared periods"
      ]
    }
  ]
}
```

ASSERTION	WHAT IT CHECKS	WHY IT MATTERS
States which items	Did it name ENG01/ENG02/ENG03 or say which items it used?	Six items in the table — only three are actually engagement items
Addresses scale consistency	Did it mention the scale changed between 2024 and 2025?	Scale went from 1-5 to 1-7 — raw averages look like a massive jump that isn't real

After saving: verify it's valid by running this in your terminal:

Windows: `python -c "import json; json.load(open('evals/my-eval.json')); print('Valid!')"`

Mac/Linux: `python3 -c "import json; json.load(open('evals/my-eval.json')); print('Valid!')"`
